#### **Abstract**:

Major winning Convolutional Neural Networks (CNNs), such as AlexNet, VGGNet, ResNet, GoogleNet, include tens to hundreds of millions of parameters, which impose considerable computation and memory overhead. This limits their practical use for training, optimization and memory efficiency. On the contrary, light-weight architectures, being proposed to address this issue, mainly suffer from low accuracy. These inefficiencies mostly stem from following an ad hoc procedure. We propose a simple architecture, called SimpleNet, based on a set of designing principles and we empirically show that SimpleNet provides a good tradeoff between the computation/memory efficiency and the accuracy. Our simple 13-layer architecture outperforms most of the deeper and complex architectures to date such as VGGNet, ResNet, and GoogleNet on several well-known benchmarks while having 2 to 25 times fewer number of parameters and operations. This makes it very handy for embedded system or system with computational and memory limitations. We achieved state-of-the-art result on standard data sets such as CIFAR10 outperforming several heavier architectures including but not limited to AlexNet on ImageNet and very good results on data sets such as CIFAR100, MNIST and SVHN. In our experiments we show that SimpleNet is more efficient in terms of computation and memory overhead compared to state of the art. Models are made available at: https://github.com/Coderx7/SimpleNet

**Keywords**: Deep learning, Convolutional neural network, classification

#### 1 Introduction

Since the resurgence of neural networks, deep learning methods have been gaining huge success in diverse fields of applications, amongst which, semantic segmentation, classification, object detection, image annotation and natural language processing are few to mention [1]. Convolutional Neural Network (CNN), as a powerful tool for representation learning, is able to discover complex structure in the given data and represent them in a hierarchical manner [2-4]. Then, there are fewer parameters to be manually engineered, among which is the network architecture. What all of the

.

<sup>&</sup>lt;sup>1</sup> Corresponding author

recent architectures have in common is the increasing depth and complexity of the network that provides better accuracy for the aforementioned tasks. The winner of the ImageNet Large Scale Visual Recognition Competition 2015 (ILSVRC) [5] has achieved its success using a very deep architecture of 152 layers [4]. The runner up also deploys a deep architecture of 22 layers [3]. This trend has proved useful in the natural language processing benchmarks as well [6].

As networks get deeper, aiming to improve their discriminative power, the computations and memory usage cost and overhead get critically expensive, which has a negative effect on their applications and expansions. Despite the existence of various techniques for improving the learning algorithm, such as different initializations algorithms [7-11], normalization and regularization method and techniques [12-16], non-linearities [9, 17-19] and data-augmentation tricks [2, 13, 20-22], they are most beneficial when used on an already well performing architecture. In addition, some of these techniques may even impose more computational and memory usage overhead [12, 14]. Therefore, it would be highly desirable to propose efficient architectures with smaller number of layers and parameters that are as good as their deeper versions. Such architectures can then be further tweaked using novel tricks and methods already known and perform even better than before.

In this paper we propose a simple efficient architecture based on a set of designing principles that outperforms almost all deeper architectures while using 2 to 25 times fewer parameters. Our architecture, SimpleNet, can be a very good candidate for many scenarios, especially for deploying in the embedded devices. It can be further compressed using methods such as DeepCompression [23] and thus its memory consumption can be decreased drastically. We impose a set of constraints for designing SimpleNet in order to achieve a well-crafted yet simple convolutional architecture. It is clear that when the model performs well in spite of all limitations, relaxing those limitations can further boost the performance with little to no effort which is very desirable. This performance boost however has direct correlation with how well an architecture is designed. A fundamentally badly designed architecture would not be able to harness the advantages because of its inherent [flawed] design.

The rest of the paper is organized as follows: Section 2 presents the most relevant works. In Section 3 we present our architecture and the set of designing principles. In Section 4 the experimental results are presented conducted on 5 major datasets (CIFAR10, CIFAR100, SVHN, MNIST, and ImageNet) and more details about the architecture and different changes pertaining to each dataset are explained. Finally, conclusions and future work are summarized in Section 5.

#### 2 Related Work

In this section, we review the latest trends in related works in the literature. We categorize them into 4 sections and explain them briefly.

# 2.1 Complex networks

Designing more effective networks were desirable and attempted from the advent of neural networks [24-26]. With the advent of deep learning methods, this desire manifested itself in the

form of creating deeper and more complex architectures [2-4, 18, 27-32]. This was first attempted and popularized by Ciresan et al [28] training a 9 layer MLP on GPU which was then practiced by other searchers [2-4, 18, 27-33].

In 2012 Krizhevsky et al [18] created a deeper version of LeNet5 [34] with 8 layers called AlexNet, unlike LeNet5, It had local contrast normalization, ReLU [18] nonlinearity instead of Tanh, and a new regularization layer called Dropout [35], this architecture achieved state of the art on ILSVRC 2012 [5]. The same year, Le et al [36] trained a gigantic network with 1 billion parameters, their work was later proceeded by Coats et al [37] which an 11 billion parameter network was trained. Both of them were ousted by much smaller network AlexNet [18].

In 2013 Lin et al [38] released their 12 layer, NIN architecture, they built micro neural networks into convolutional neural network using 1x1 filters. They also used global pooling instead of fully connected layers at the end acting as a structural regularizer that explicitly enforces feature maps to be confidence maps of concepts. In 2014 VGGNet by Simonyan et al [2] introduced several architectures, with increasing depth, 11 being the shallowest and 19 the deepest, they used 3x3 conv filters, and showed that stacking smaller filters results in better non-linearity and achieves better accuracy. They showed the deeper, the better. The same year, GoogleNet [3] was released by Szegedy et al, with 56 convolutional layers making up a 22 modular layered network, their architecture was made up of convolutional layers with 1x1, 3x3 and 5x5 filters which they call, an *inception module*. Using this architecture they could decrease the number of parameters drastically compared to former architectures. They ranked first in ImageNet challenge that year. They later revised their architecture and used two consecutive 3x3 conv layers with 128 filters instead of the previous 5x5 filter layers, they also used a technique called Batch-normalization [14] for reducing internal covariate shift. This technique provided improvements in several sections which is explained thoroughly in [14]. They achieved state of the art results in ImageNet challenge.

In 2015 prior to GoogleNet achieving the state of the art on ImageNet, He et al [9], released their paper in which they used a ReLU variant called, Parametric RELU (PReLU) to improve model fitting, they also created a initialization method specifically aimed at rectified nonlinearities, by which they could train deeper architectures better. Using these techniques, they could train a slightly modified version of VGGNet19 [2] architecture and achieved state of the art result on ImageNet. At the end of 2015, they proposed a deep architecture of 152 layers, called Residual Network (ResNet) [4] which was built on top their previous findings and achieved state of the art on ImageNet previously held by themselves. In ResNet they used what they call residual blocks in which layers are let to fit a residual mapping. They also used shortcut connections to perform identity mapping. This made them capable of training deeper networks easily and gain more accuracy by going deeper without becoming more complex. In fact their model is less complex than the much shallower VGGNet [2] which they previously used. They investigated architectures with 1000 layers as well. Later Huang et al [39] further enhanced ResNet with stochastic depth, where they used a training procedure, in which they would train a shorter network and then at test time, use a deeper architecture. Using this method they could train even deeper architectures and also achieve state of the art on CIFAR dataset.

Prior to the residual network, Srivastava et al [30] released their Long Short Term Memory (LSTM) recurrent network inspired *highway networks* in which they used the initialization method proposed by He et al [9] and created a special architecture that uses adaptive gating units to regulate the flow of information through the network. They created a 100 layer and also experimented with a 1k layer network and reported the easy training of such network compared to the plain ones. Their contribution was to show that deeper architectures can be trained with Simple stochastic gradient descent.

In 2016 Szegedy et al [40] investigated the effectiveness of combining residual connections with their inception v3 architecture. They gave empirical evidence that training with residual connections accelerates the training of Inception networks significantly, and reported that residual Inception networks outperform similarly expensive Inception networks by a thin margin. With these variations the single-frame recognition performance on the ILSVRC 2012 classification task [5] improves significantly. With an ensemble of three residual and one Inception-v4, they achieved 3.08 percent top-5 error on the test set of the ImageNet classification challenge. The same year, Zagoria et al [31] ran a detailed experiment on residual nets [4] and came up with a novel architecture called *Wide Residual Net* (WRN) where instead of a thin deep network, they increased the width of the network in favor of its depth(decreased the depth). They showed that the new architecture does not suffer from the *diminishing feature reuse problem* [30] and slow training time. They report that a 16 layer wide residual network, outperforms any previous residual network architectures. They experimented with varying depth of their architecture from 10 to 40 layers and achieved state of the art result on CIFAR10, 100 and SVHN.

# 2.2 Model compression

The computational and memory usage overhead caused by such practices, limits the expansion and applications of deep learning methods. There have been several attempts in the literature to get around such problems. One of them is model compression in which it is tried to reduce the computational overhead at inference time. It was first researched by Bucila et al [41], where they tried to create a network that performs like a complex and large ensemble. In their method they used the ensemble to label unlabeled data with which they train the new neural network, thus learning the mappings learned by the ensemble and achieving similar accuracy. This idea is further worked on by Ba & Caruana [42]. They went into the same direction but this time they tried to compress deep and wide networks into shallower but even wider ones. Hinton et al [10] introduced their model compression model, called Knowledge Distillation (KD), which introduces a teacher/student paradigm for transferring the knowledge from a deep complex teacher model or an ensemble of such, to less complex yet still similarly deep but fine-grained student models, where each student model can provide similar performance overall and perform better on fine-grained classes where the teacher model confuses. And thus eases the training of deep networks. Inspired by Hinton et al [10], Romero et al [43] proposed a novel architecture to address what they referred to as not taking advantage of depth in the previous works related to Convolutional Neural Networks model compression. Up until then, all previous works tried to compress a teacher

network or an ensemble of networks into either networks of similar width and depth or into shallower and wider ones. They proposed a novel approach to train thin and deep networks, called *FitNets*, to compress wide and shallower (but still deep) networks. Their method is based on Knowledge Distillation (KD)[10] and extends the idea to allow for thinner and deeper student models. They introduce *intermediate-level hints* from the teacher hidden layers to guide the training process of the student, they showed that their model achieves the same or better accuracy than the teacher models.

## 2.3 Network Pruning

In late 2015 Han et al[23] released their work on model compression. They introduced "deep compression", a three stage pipeline: pruning, trained quantization and Huffman coding, that work together to reduce the storage requirement of neural networks by 35 to 49 times without affecting their accuracy. In their method, the network is first pruned by learning only the important connections. Next, the weights are quantized to enforce weight sharing, finally, the Huffman coding is applied. After the first two steps they retrain the network to fine tune the remaining connections and the quantized centroids. Pruning, reduces the number of connections by 9 to 13 times; Quantization then reduces the number of bits that represent each connection from 32 to 5. On the ImageNet dataset, their method reduced the storage required by AlexNet by 35 times, from 240MB to 6.9MB, without loss of accuracy.

# 2.4 Light weight architectures

In 2015 Springenberg et al [44] released their paper where the effectiveness of simple architectures was investigated. The authors intended to come up with a simplified architecture, not necessarily shallower, that would perform better than at the time, more complex networks, they proposed different versions of their architecture and studied their characteristics, and later using a 17 layer version of their architecture they achieved a result very close to state of the art on CIFAR10 with intense data-augmentation.

In 2016 Iandola et al[45] released their paper in which they proposed a novel architecture called, *squeezenet*, a small CNN architecture that achieves AlexNet-level[18] accuracy on ImageNet With 50 times fewer parameters. To our knowledge this is the first architecture that tried to be small and yet be able to achieve a good accuracy.

In this paper, we tried to come up with a simple architecture which exhibits the best characteristics of these works and propose a 13 layer convolution network that achieves state of the art result on CIFAR10<sup>2</sup>. Our network has much fewer parameters (2 to 25 times less) compared to all previous deep architectures, and performs either superior to them or on par despite the huge difference in number of parameters and depth. For those architectures such as *squeezenet/fitnet* where the number of parameters is less than ours but also are deeper, our network accuracy is far superior to

<sup>&</sup>lt;sup>2</sup> While preparing our paper we found out, our record was beaten by Wide Residual Net, which we then addressed in related works. We still have the state of the art record without data-augmentation as of zero padding and normalization.

what can be achieved with such networks. Our architecture is also the smallest (depth wise) architecture that both has a small number of parameters compared to all leading deep architectures, and also unlike previous architectures such as squeezenet or fitnet, gives higher or very competitive performance against all deep architectures.

Our model then can be compressed using deep compression techniques and be further enhanced, resulting in a very good candidate for many scenarios.

## 3 Proposed Architecture

We propose a simple convolutional network with 13 layers. The network employs a heterogeneous design utilizing 3x3 filters for convolutional layer and 2x2 filters for pooling operations. Figure 1 illustrates the proposed architecture.

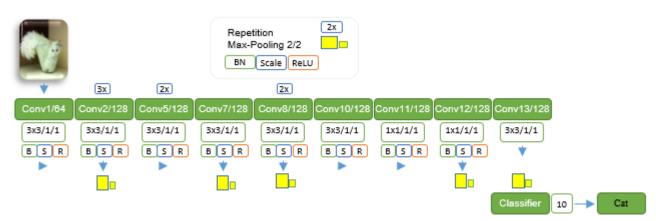

Figure 1 showing the base architecture with no drop-out

The only layers which do not use 3x3 filters are 11<sup>th</sup> and 12<sup>th</sup> layers, these layers, utilize 1x1 convolutional filters.

Feature-map down-sampling is carried out using 2x2 max-pooling layers with stride of 2. In order to cope with the problem of vanishing gradient and also over-fitting, we used batch-normalization with moving average fraction of 0.95 before any ReLU non-linearity. We also used weight decay as regularizer. A second version of the architecture uses dropout to cope with over-fitting. Table 1 shows different architectures and their statistics, among which our architecture has the lowest number of parameters and operations. The extended list is provided in the appendix.

Model	AlexNet Goo		oogleNet ResNet152		NIN	Ours		
#Param	60M	7M	60M	138M	7.6M	5.4M		
#OP	1140M	1600M	11300M	15740M	1100M	652M		
Storage (MB)	217	51	230	512.24	29	20		

Table 1 showing different architectures statistics

#### 3.2 Design intuition:

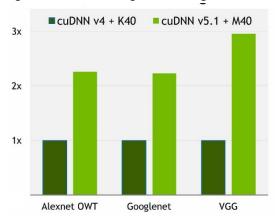

We used several principles in our work that helped us manage different issues much better and achieve desirable results. These principles are as follows:

- i. **Minimum Allocation:** In order to better manage the computational overhead, parameter utilization efficiency, and also network generalization power, it's recommended to build a thin but deeper network instead of a wide but shallower one. Fewer number of neurons decreases the chance of over fitting and together with an enough depth it increases the generalization power. The depth needs to be increased gradually, however choosing a randomly deep architecture will result in more parameters and ultimately yield the same in-efficiency this principle is trying to avoid.
- ii. **Gradual Expansion:** Start with a small network, expand it into a deep but thinner network gradually. Not the number of depth nor the number of parameters are good indicators of how a network should perform. They are neutral factors that are only beneficial when utilized mindfully, if enough care is not taken, the design would be an inefficient network imposing un-wanted overhead. In order to utilize both depth and parameters more efficiently, design the architecture in a symmetric and gradual fashion, i.e. instead of creating a network with a random yet great depth, and large number of neurons per layer, start with a small and thin network then gradually add more symmetric layers. Expand the network to reach a cone shaped form. A Large degree of invariance to geometric transformations of the input can be achieved with this progressive reduction of spatial resolution compensated by a progressive increase of the richness of the representation (the number of feature maps), hence getting a conned shape, that's one of the reasons why deeper is better) [34]. A network with smaller number of neurons per layer, coupled with more layers with the same characteristic, tends to work better compared to a network with shallower but wider layers.
- iii. **Homogeneous Groups of Layers:** Instead of thinking in layers, think and design in group of homogeneous layers. The idea is to have several homogeneous groups of layers, each with gradually more width. A coned shaped network i.e. a network in which layers have more neurons as they get closer to the end of the network, works much better. The symmetric and homogeneous design, allows to easily manage the number of parameters a network will withhold and also provide better information pools for each semantic level.
- iv. **Local Correlation Preservation:** Preserve locality information throughout the network as much as possible by avoiding 1x1 kernels in early layers. The corner stone of CNN success lies in local correlation preservation. Avoid using 1x1 filters or fully connected layers where locality of information matters. This includes exclusively the early layers in the network. 1x1 kernels have several desirable characteristics such as increasing networks non-linearity and feature fusion [38] which increases abstraction level, but they also ignore any local correlation in the input. Since they do not consider any neighborhood in the input and only take channels into account, they distort valuable local information. Preferably use 1x1 kernels at the end of the network or if one intends on using tricks such as bottleneck employed by GoogleNet [3] and ResNet [4], use considerably more layers with skip connections to compensate the loss in information. This however will increase the number of operations thus imposing more computation overhead. Therefor pay necessary

- precautions when using such features. It is suggested to replace 1x1 filters with 2x2 if one plans on using them other than the end of the network. Using 2x2 filters both help to reduce the number of parameters and also to retain neighborhood information.
- v. **Maximum Information Utilization:** Harness the most out of what you have by avoiding rapid down sampling especially in early layers. To increase a network's discriminability power, more information needs to be made available. This can be achieved either by a larger dataset or larger feature-maps. If larger dataset is not feasible, the existing training samples must be efficiently harnessed. Larger feature-maps especially in early layers, provide more valuable information to the network compared to smaller ones. With the same depth and number of parameters, a network which utilizes bigger feature-maps achieves a higher accuracy. Therefor instead of increasing the complexity of a network by increasing its depth and number of parameters, one can leverage more performance/accuracy by simply using larger input dimensions or avoiding rapid early down-sampling. This is a good technique to keep the complexity of the network in check and increase the performance/accuracy.
- **Maximum Performance Utilization:** Use 3x3, and follow established industrial trends. vi. For an architecture to be easily useable and widely practical, it needs to perform fast and decently. By taking into account the current improvements in underlying libraries, designing better performing and more efficient architectures are possible. Using 3x3 filters, apart from already known benefits [2], allows to achieve a substantial boost in performance when using NVidia's Cudnnv5.x library. A speed up of about 2.7x compared to the former v4 version.<sup>3</sup> This is illustrated in Figure 2. This ability to harness every amount of performance is a decisive criterion when it comes to production and industry. A fast and robust performance translates into, less time, decreased cost and ultimately a higher profit for business owners. Apart from the performance point of view, on one hand larger kernels do not provide the same efficiency per parameter as a 3x3 kernel does. It may be theorized that since larger kernels capture a larger area of neighborhood in the input, using them may help in ignoring noises and thus capturing better features, ultimately improving performance, but in actuality the overhead they impose in addition to the loss in information they cause make them not an ideal choice. This makes the efficiency per parameter to decrease and causes unnecessary computational burden. Smaller kernels on the other hand do not capture local correlations as well as 3x3 kernels. Detecting boundaries and orientations are better done using a 3x3 kernel in addition to the performance gains achieved by using 3x3.

<sup>&</sup>lt;sup>3</sup> https://developer.nvidia.com/cudnn-whatsnew

Figure 2 showing 2.7x faster training when using 3x3 kernels using cudnnv5.x

- vii. **Rapid Prototyping: Test** the architecture with different learning policies before altering it. Most of the time, it's not the architecture that needs to be change, rather it's the optimization policy. A badly chosen optimization policy leads to inefficient convergence, wasting network resources. Simple things such as learning rates and regularization methods, usually have an adverse effect if not tuned correctly. Therefor it is first suggested to use an automated optimization policy to run quick tests and when the architecture is finalized, the optimization policy is carefully tuned to maximize network performance.
- **viii. 8. Experiment Isolation: Conduct** experiments under fair and equal conditions. When testing a new feature, make sure only the new feature is being tested. For example when testing 5x5 vs 3x3, the overall network entropy must be equal. It is usually neglected in different experiments and features or changes are not tested in isolation or better said, under a fair and equal conditions. Throughout experimentation, it is easy to slip and lose track of the changes, some architectures contain more parameters/entropy, some become deeper etc. In order to effectively assess a specific feature and its effectiveness in the architectural design, it is important to keep track of changes the feature causes and take necessary action to provide the needed environment to conduct the test.
- ix. **Minimum Entropy:** Like previous principle, here we explain about the generalization power and why lower entropy matters. It is true that the more parameter a network withholds, the faster it can converge, and the more accuracy it can achieve, but it will overfit more as well. A model with fewer number of parameters which provides better results or performs comparable to heavier models indicates the fact that, the network has learnt much better features based on which it is making its decision. In other words, by imposing more constrains on the amount of entropy a network has, we force the network to find and use much better and more robust features. This specifically manifests itself in the generalization power, since the network decisions are based on more important and more distinctive (discriminative) features (and fewer noisy ones as well) it can perform much better compared to a network with higher number of parameters which would easily over fit as well.

x. **Final Regulation Stage:** While we try to formulate the best ways to achieve better accuracy in the form of rules or guidelines, they are not necessarily meant to be aggressively followed in all cases. These guidelines are meant to help achieve a good compromise between performance and the imposed overhead. Therefor start by designing according to the guidelines and then step in to alter the architecture in order to get the best compromise between performance/overhead. In order to better tune your architecture, try not to alter or deviate a lot from multiple guidelines at once. Work on one aspect at a time until the desired outcome is achieved. After all it's all about the well balanced compromise between performance / imposed overhead according to one's specific needs.

As we have already briefly discussed in previous sections, the current trend in the community, has been to start with a deep and big architecture and then use different regularization methods to cope with over-fitting. The intuition behind such trend is that, it is naturally difficult to come up with an architecture with the right number of parameters/depth that suites exactly ones data requirements. While such intuition is plausible and correct, it is not without flaws.

One of the issues is the fact that, there are many use cases and applications for which there is not a huge dataset (such as ImageNet e.g.) available. Apart from the fact that less computation and memory overhead is always desirable for any circumstances and results in decreased costs, the majority of applications have access to medium/small sized datasets and yet they are already exploiting the benefits of deep learning and achieving either state of the art or very outstanding results. Individuals coming from this background, have two paths before them when they want to initiate a deep learning related project:

- 1. They either are going to design their own architecture which is difficult and time-consuming and has its own share of issues.
- 2. Use one of the existing heavy but very powerful architectures that won competitions such as ImageNet or performed well on a related field of their interest.

Using these kinds of architectures impose a lot of overhead and users should also bear the cost of coping with the resulting over-fitting. It adversely affects training time, making it more time and resource consuming. When someone opts to use fine-tuning on his dataset for any number of reasons such as having a small dataset, fine-tuning for a new application, etc. they are bound to also bear the issues caused by such deep and heavy architectures, computational, memory and time overhead.

Therefor it makes more sense to have a less computationally expensive architecture which provides higher or comparable accuracy compared to the heavier counter parts. The lowered computational overhead results in a decreased time and power consumption which is a decisive factor for mobile applications. Apart from such benefits, reliance on better and more robust features is another important reason to opt for such networks.

#### 4 Experiments

We experimented on CIFAR-10/100 [46], SVHN [47], MNIST [34] and ImageNet [5] datasets in order to evaluate and compare our architecture against the top ranking methods and deeper models that also experimented on such datasets. We only used simple data augmentation of zero padding, and mirroring on CIFAR10/100. Other experiments on MNIST [34], SVHN [47] and ImageNet [5] datasets are conducted without data-augmentation. In our experiments we used one configuration for all datasets and, we did not fine-tune anything except CIFAR10. We did this to see how this configuration can perform with no or slightest change in different scenarios. We used Caffe framework [48] for training our architecture and ran our experiments on a system with Intel Pentium G3220 CPU ,14 Gigabyte of RAM and NVidia GTX980.

#### 4.1 CIFAR10/100

The CIFAR10/100 datasets includes 60,000 color images of which 50,000 belong to training set and 10,000 are reserved for testing (validation). These images are divided into 10 and 100 classes respectively and classification performance is evaluated using top-1 error. Table 2 shows the results achieved by different architectures.

We tried two different configurations for CIFAR10 experiment, one with no data-augmentation i.e. zero-padding and normalization and another one using data-augmentation. We name them Arch1 and Arch2 respectively. The Arc1 achieves a new state of the art in CIFAR10 when no data-augmentation is used and the Arc2 achieves 95.32. In addition to the normal architecture, we used a modified version on cifar100 and achieved 74.86 with data-augmentation. Since it had more parameters we did not include it in the following table. More results are provided in the appendix.

Table 2 showing Top CIFAR10/100 results

Method	#Params	CIFAR10	CIFAR100
VGGNet(original 16L)[49]/Enhanced	138m	91.4 / 92.45	-
ResNet-110L[4] / 1202L[4] *	1.7m/10.2m	93.57 / 92.07	74.84 / 72.18

Our Architecture 🏻 4	5.48m	95.32	73.42

<sup>&</sup>lt;sup>4</sup> Data-augmentation method used by stochastic depth paper: https://github.com/Pastromhaug/caffe-stochastic-depth.

\*Note that the Fractional max pooling[13] uses deeper architectures and also uses extreme data augmentation. means No zero-padding or normalization with dropout and means Standard data-augmentation- with dropout. To our knowledge, our architecture has the state of the art result, without aforementioned data-augmentations.

#### 4.3 MNIST

The MNIST dataset [34] consists of 70,000 28x28 grayscale images of handwritten digits 0 to 9, of which 60,000 are used for training and 10,000 are used for testing. We didn't use any data augmentation on this dataset, and yet achieved the second highest score without data-augmentation and fine-tuning. We also slimmed our architecture to have only 300K parameters and achieved 99.72% accuracy beating all previous larger and heavier architectures. Table 3 shows the current state of the art results for MNIST.

Table 3 showing MNIST results

· · · · · · · · · · · · · · · · · · ·	
Method	Error rate
Regularization of Neural Networks using DropConnect[16]**	0.21%
Multi-column Deep Neural Networks for Image Classification[53]**	0.23%

Our architecture *	0.25%

<sup>\*</sup>Note that we didn't intend on achieving the state of the art performance here, as we already pointed out in the prior sections, we wanted to experiment if the architecture does perform nicely without any changes

#### **4.4 SVHN**

The SVHN dataset [47] is a real-world image dataset, obtained from house numbers in Google Street View images. It consists of 630,420 32x32 color images of which 73,257 images are used for training, 26,032 images are used for testing and the other 531,131 images are used for extra training. Like [12, 38, 39] we only used the training and testing sets for our experiments and didn't use any data-augmentation. We also used the slimmed version and got a very good result. Best results are presented in table 4.

<sup>\*\*</sup>Achieved using an ensemble or extreme data-augmentation

Table 4 showing SVHN results

Method	Error
Network in Network	2.35
Deeply Supervised Net	1.92
ResNet (reported by Huang et al. (2016))	2.01
ResNet with Stochastic Depth	1.75
Wide ResNet	1.64
Our architecture	1.79

#### 4.5 ImageNet

ImageNet[5] dataset includes images of 1000 classes, and is split into three sets: 1.2M training images, 50K validation images, and 100K testing images. The classification performance is evaluated using two measures: the top-1 and top-5 error. We used the same architecture without any dropout and didn't tune any parameters. We just used plain SGD to see how it performs with a simple learning policy. Table 5 shows the latest result from the ongoing test.

Table 5 showing ImageNet2012 results

8	
Method	T1/T5
AlexNet(60M)	57.2/80.3
Squeezenet(1.3M)	57.5/80.3
Network in Network(7.5M)	59.36/-
VGGNet16(138M)	70.5
GoogleNet(8M)	68.7
Wide ResNet(11.7M)	69.6/89.07
Our architecture*	60.88/83.46

<sup>\*</sup>Trained only for 300K (still training)

#### 4.6 Extended test: Testing the architecture with fewer number of parameters:

Some architectures can't scale well when their processing capacity decreases. This shows the design is not robust enough to efficiently use its processing capacity. We tried a slimmed version of our architecture which has only 300K parameters to see how it performs and whether it's still efficient. The network also does not use any dropout. Table 6 shows the results for our architecture with only 300K parameters in comparison to other deeper and heavier architectures with 2 to 20 times more parameters.

Table 6-Slimmed version Results on Different Datasets

Model	О	urs	Maxout	DSN	ALLCNN	dasNet	ResNet(32)	WRN	NIN
#Param	310K	460K	6M	1M	1.3M	6M	475K	600K	1M
CIFAR10	91.98	92.33	90.62	92.03	92.75	90.78	91.6	93.15	91.19
CIFAR100	64.68	66.82	65.46	65.43	66.29	66.22	67.37	69.11	-
Other datas	Other datasets						Our r	esult	
MNIST(310K)*						99.	72		
SVHN(310K)*					97.63				
ImageNet(310K) **					37.34/63.4				

\*Since we presented their results in their respective sections, we avoided mentioning the results here again.

#### 5 Conclusion

In this paper, we proposed a set of architectural design guidelines and a resulting simple convolution architecture that takes advantage of the simplicity in its design and outperforms deeper and more complex architectures in spite of having considerably fewer number of parameters and operations. We showed that a good design should be able to efficiently use its processing capacity and showed that our slimmed version of the architecture with much fewer number of parameters (300K) also outperforms deeper and or heavier architectures. Intentionally limiting ourselves to a few layers and basic elements for designing an architecture allowed us to overlook the unnecessary details and concentrate on the critical aspects of the architecture, keeping the computation in check and achieve high efficiency.

We tried to show the importance of simplicity and optimization using our experiments and also encourage more researchers to study the vast design space of convolutional neural network in an effort to find more and better guidelines to make or propose better performing architectures with much less overhead. This will hopefully greatly help expanding deep learning related methods and applications, making them more viable in more situations.

In this paper, we had to contend ourselves to a few configurations. We would like to extend our work by experimenting on new applications and design choices especially using the latest achievements about deep architectures in the literature and present our new findings.

# 6 Acknowledgement

We would like to thank Dr. Ali Diba, the CEO of Sensifai for his great help and cooperation in this work. We would also like to thank Dr. Hamed Pirsiavash for his insightful comments and Dr. Reza Saadati and Dr. Javad Vahidi for their help.

<sup>\*\*</sup>ImageNet result belongs to the latest iteration of a still ongoing training.

# Appendix:

## A short discussion: The importance of Optimization plans

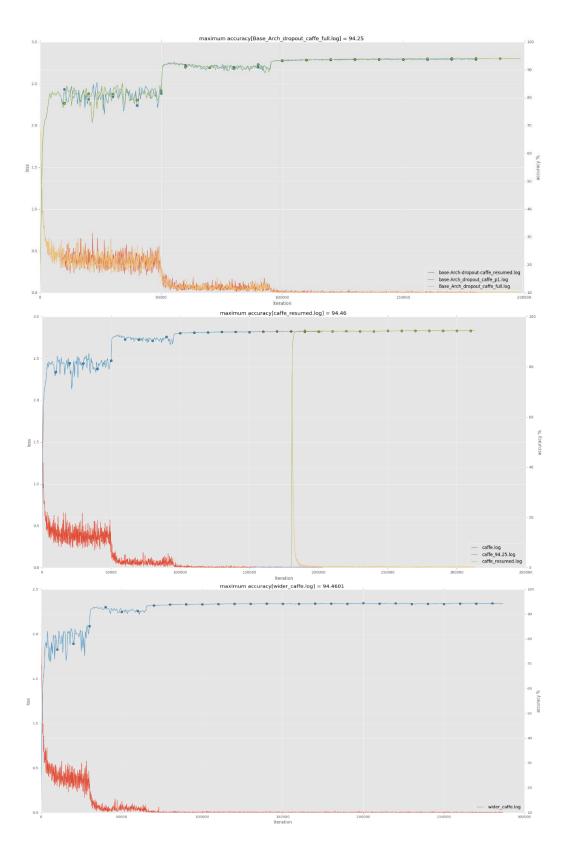

Different configurations are sampled and depicted below, which show an obvious but yet neglected point. That is all of the results below, show the very same architecture, performing differently when differently optimized. The optimization process needless to say is not a complex procedure. Looking at the charts below and previous results, it can be confidently said that a properly crafted architecture can let a significant capacity of itself to go to waste, by poor optimization decisions. Yet again a well-chosen optimization policy can make a simple trivial architecture utilize the most out of the capacity it withholds and outperform all deeper architectures with several times less parameters!

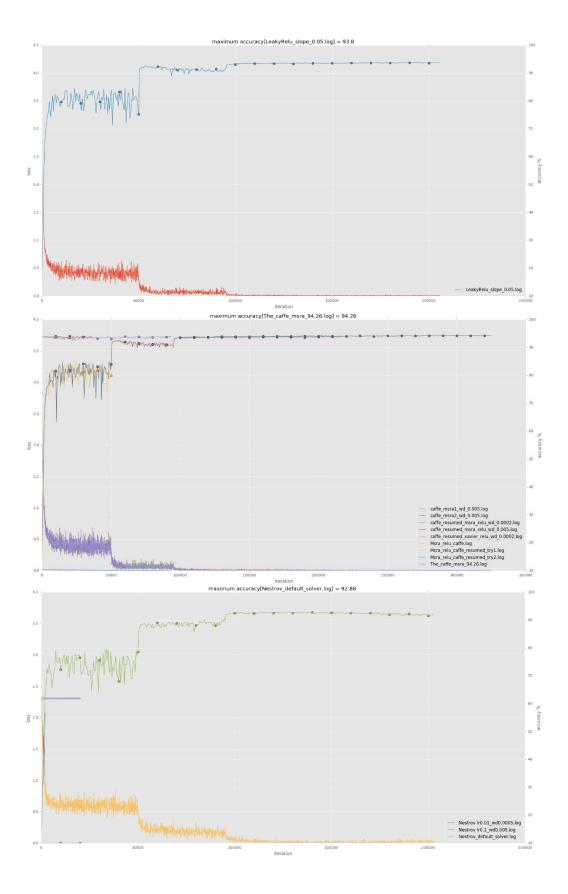

The fact is that there should be a sensible level of hierarchy of features and enough number of parameters so that in accordance to the input data, the network has the potential /capacity to provide a desirable answer. So far, the recent trend in CNN design has been redirected toward training very deep and almost always heavier architectures in order to attain good performance, and in doing so, the optimization part in our humble opinion is neglected, and the resulting outcome make the spectrum of their practical uses yet more limited.

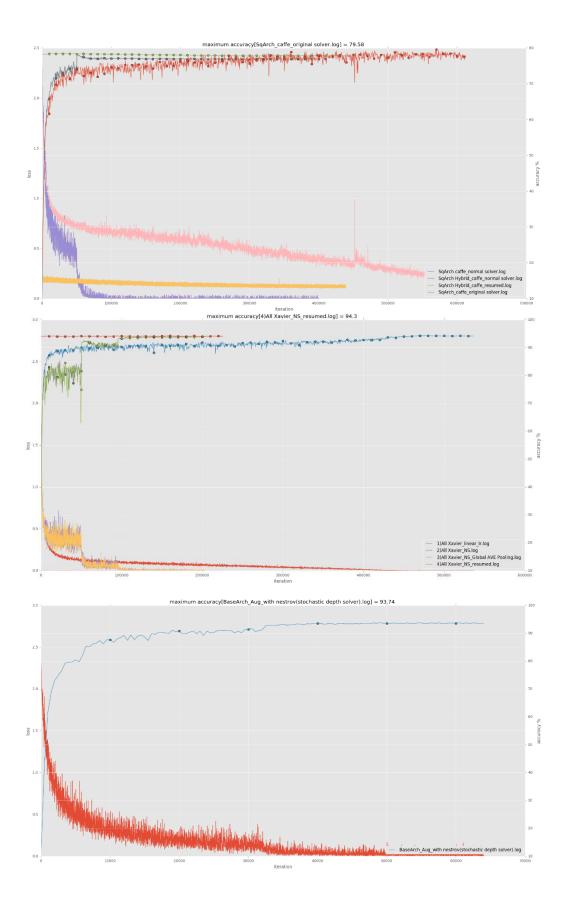

Looking at the results in our experiments and also looking at examples such as NIN[38], MIN[51], RCNN-96[57] which at the time outperformed heavier architectures, or stochastic depth[39] which enhanced ResNet performance, we can probably say with confidence that going *very* deep is not an essential criterion to gain better performance.

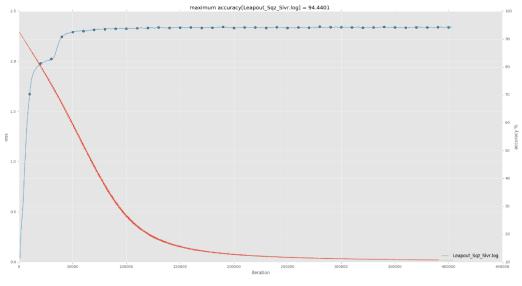

Although an optimal depth has yet to be discovered, it is known that these deep architectures are far from being optimal and a lot of redundancy takes place while training. Therefor we believe instead of going deeper, one should concentrate more on the optimization policy they seek to incorporate.

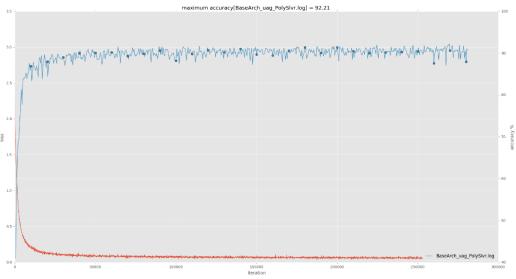

Our attempt practically shows that a much shallower and simpler architecture can still provide very good results, outperforming all of these deep networks or at the very least work on par. Ultimately this means that the improvements in this regard lies in the optimization plans rather than a blindly chosen depth of the network.

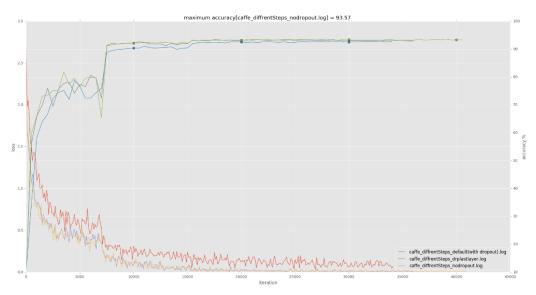

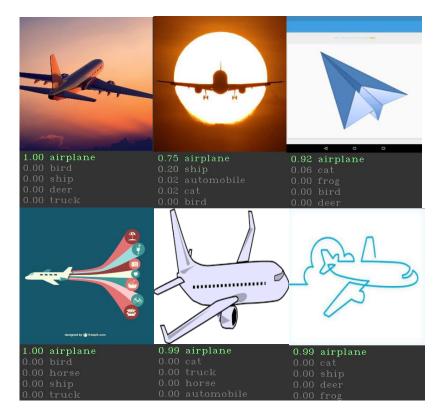

# **Generalization Samples:**

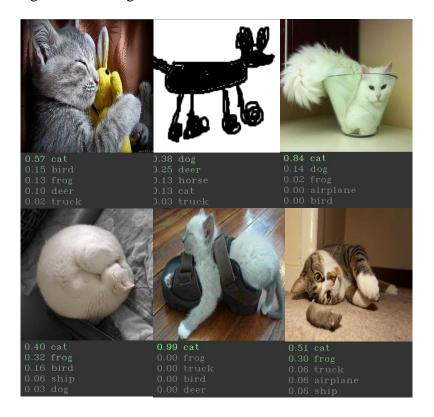

In this section we show some examples from CIFAR10 dataset that the network classifies correctly despite the huge difference in their appearance with other samples and also those present in training set. These pictures are taken using Deep Visualization Toolbox<sup>5</sup> by Yosinski et al[58] and early un-augmented version model.

Figure 6 some airplanes pictures with completely different apperance that the network classfies very well

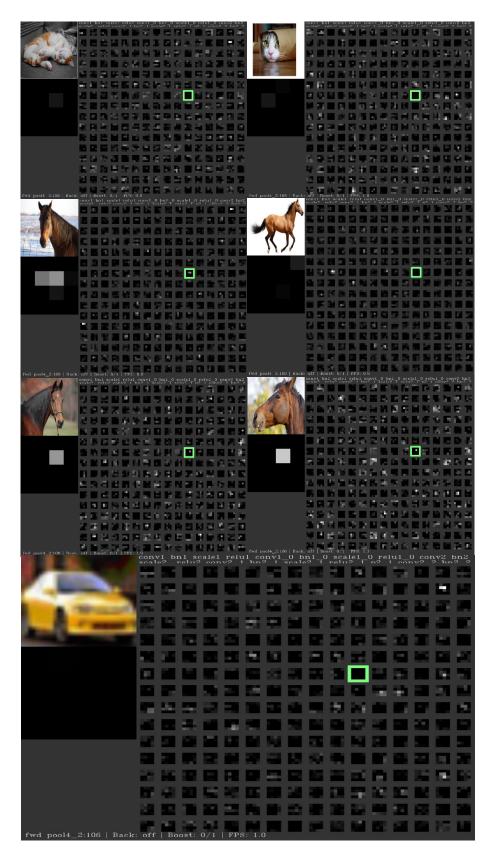

<sup>&</sup>lt;sup>5</sup> https://github.com/yosinski/deep-visualization-toolbox

Figure 7 showing some cat images with a lot of deformations and also a drawing of animal

An interesting point in the above picture lies in the black dog like drawing and the interesting job the network does on the weird drawing we drew! We intentionally drew a figure that does look like to several categories and thus wanted to test how it looks like to the network and whether network uses sensible features to distinguish each class. Interestingly the network tries its best and classifies the image according to the prominent features it finds in the picture. Similarity to the animals in the first for predictions and then a truck at the end! The circled shape of the weird animal's legs is used as an indication of the truck!

Figure 8 showing a head detector the network learned which responds when seeing a head in images of animals it has never seen. The same detector does not activate when confronted with an image of a car!

<sup>\*</sup>Inception v3, v4 and Inception-ResNetV2 did not have any Caffe model, so we reported their size related information from mxnet<sup>6</sup> and tensorflow<sup>7</sup> respectively. Inception-ResNet-V2 would take 60 days of training with 2 Titan X to achieve the reported accuracy<sup>8</sup>

As it can be seen, our architecture both has much fewer number of parameters (with an exception of squeezenet) and also much fewer number of operations.
